18/8/26 Reflection

Today's lecture involved the construction of squares using computer graphics as well as the study of how these squares are defined using coordinates. It was discovered that prior to constructing a square, it is imperative to determine the top, bottom, left, and right edges of the square.

Using the center and dimensions of the square, all four coordinate points can be determined. Our work included the following elements:

- Center: (Cx, Cy)
- UL: Upper Left
- UR: Upper Right
- LL: Lower Left
- LR: Lower Right
- After determination of the four points, the square will be constructed using these points.
- Physical units were not needed; coordinates are sufficient.

In addition to that, we also got an insight into the structure of the Java project and learned about the roles played by various files and directories.

- src → holds the source code
- pom.xml → holds Maven project information
- .gitignore → holds files/directories which Git will ignore
- target → holds build files

- main → holds the code for the application
- test → holds testing code of the application

The class also covered three Java frameworks for graphics: AWT, Swing, and JavaFX. AWT and the Graphics class in particular were covered in class. The Graphics class is used to draw graphics objects.

Other concepts covered include the distinction between object variables and static/class variables. An object variable is an attribute that belongs to an object, meaning that each object has its own value. However, a static/class variable is an attribute that is common to all objects within the same class.

Thus, the professor helped us link the math term of coordinates and points to real Java programming. We realized that by recognizing the four corners of the square, understanding the project architecture, and working with Java Graphics classes we can program graphical objects.
